To prove that this circuit arrangement made the detector a potential operated device, four of these detector circuits, each with its separate indicating instrument, were arranged so that they could be simultaneously in connection with an antenna circuit tuned to distant signals. It was found that in no case was the signal intensity in the first set decreased by connecting on one or all of the other three. Moreover the signals in all four receivers were approximately equal. The slight inequalities were due to difference in sensitiveness of the separate detectors. The effect on a single indicator could be proportionally increased by connecting it to the secondary winding of a transformer, having separate primaries which were connected to the separate detectors. Theoretically this circuit furnishes a means of securing any received current desired, simply by connecting a sufficient number of units. With these circuits the vacuum detector can be adjusted so that the paralyzing effect of strong signals is not encountered. This makes the detector electrically stable and is a very important feature. The detector can also be adjusted so that the local battery current, which we shall call the field current, increases or decreases as desired, when the signals arrive. We will not attempt to give a theoretical consideration of the detector s action, but simply explain the various circuits employed....
